

To replicate my results found in section 5 of my report, you will need to run `vs.py` (no arguments needed). This will run both the baseline solution (seen in `lab3solution.py`) and my evolutionary solution (seen in `main.py`) 30 times on each dataset in the `datasets` folder and print out:

- median for the baseline and evolutionary solution
- 1st quartile for the baseline and evolutionary solution
- 3rd quartile for the baseline and evolutionary solution
- p-value given when comparing the set of results from both solutions using the Wilcoxon rank-sum test
- Whether we reject H_0 at the level of significance 0.05 using the given p value

for each dataset. One run of this gave all information inside of the table in Section 5 of my report.
